

1. PROJECT OVERVIEW

- **Project Title:** ComicCraft - AI Comic Story Creator using Gemini Models

2. SYSTEM EVOLUTION & BASELINE :

The current Minimum Viable Product (MVP) operates efficiently as a local web app capable of generating 5-panel short comics. It successfully validates the concept of chained Generative AI. To transition this academic prototype into a commercial-grade Software-as-a-Service (SaaS) platform, several scaling strategies are planned.

3. STRATEGIES FOR COMMERCIALIZATION & SCALING

- **Serverless Architecture & Cloud Hosting:** Migrating the FastAPI application from local hosting to managed cloud environments (like AWS Lambda or Google Cloud Run) to seamlessly handle high-concurrency traffic from thousands of users.
- **Persistent Cloud Storage & Authentication:** Implementing a backend database (such as MongoDB or PostgreSQL) with user login capabilities. This will allow users to maintain a persistent digital library of their comic books online.
- **Long-Form Generation Logic:** Upgrading the backend routing to handle recursive AI prompting, enabling the generation of massive 20+ page graphic novels with interconnected, branching storylines.
- **Advanced Character Consistency (LoRA):** Integrating Low-Rank Adaptation (LoRA) models into the Stable Diffusion pipeline. This is a crucial future upgrade that will guarantee 100% facial and clothing consistency for the protagonist across every single generated panel.
- **Post-Generation Editing Canvas:** Developing a drag-and-drop web interface that allows users to manually tweak the AI's generated text, or request regenerations for specific image panels, before triggering the final PDF download.
